49. Vegetable-tanned collagen fibres used in the manufacture of artificial leather — Vöröscseréda kollagénrostok felhasználása mesterségesbőr előállításához — L. Radnóti (Leather and Shoe Industry — Bör- és Cipőiparai) — Vol. 2, 1952, No. 6, pp. 183—188, 10 figs., 3 tabs.)

Due to the individual properties and specific structures of bark-tanned collagen fibres, a chemical modification is necessary. With the modification, the collagen fibres obtain a satisfactory specific surface without influencing the fibre length. A shredding operation precedes the chemical modification. For this purpose slicing is the most adequate. The sliced raw material is pulped in a Hollander. The chemical modification preceding slicing is primarily detanning. The vegetable tanned collagen fibres contain large quantities (35%) of tannin which cause closely connected bridge bonds, thus rendering the fibres unsuitable for pulping. Upon the removal of the tannin the bridge bonds between the peptide groups and tannins break up. This action can be best achieved by the use of basic materials. By rechroming subsequent to detanning, the fibre resistance to shearing is increased and the sensitivity of vegetable tanned collagen fibres to heat is reduced. A further increase in fibre resistance can be obtained by

fat liquoring which at the same time has a good lubricating effect. Chemical modifications increase the resistance of fibres by 120% as compared to the untreated fibres. Chemical modification affords the opportunity to obtain a raw material from vegetable-tanned collagen fibres comparable to the best chrome-tanned collagen fibres used in the manufacture of artificial leather. P. Brugger

RADNOTI L.

H U N G .

105. The utilization of condensation resins in the manufacture of fibre leather — L. Radnóti (*Bor és Cipőtechnika* — Vol. 4, 1954, No. 4, pp. 97—103, 7 figs.)

Bonding with synthetic resins (either by themselves or combined with synthetic latices) enhances the strength of Leca type artificial leather sheets and ensures a broader use of fibre leather products. Polymeric substances prepared by condensation reactions may be classified (on the basis of their monomeric mother substances) as follows: (1) urea type resins, on the basis of urea-formaldehyde and melamine-formaldehyde; (2) phenolic type resins, on the basis of phenol and its homologues, regardless of whether resins based on urea or phenolic type novolaks are employed. In the fibre leather industry synthetic resins can be applied only in the form of aqueous dispersions. The resins can be dispersed by melting with water or peptizing with alkaline solutions. Vegetable tanned leather fibres bonded with 5 to 7% melamine based resin produce a leather substitute which possesses good water resistance and fine physical properties. The combination of chrome tanned leather fibres with melamine yielded poor results. An artificial leather which meets the requirements of excellent strength and flexural properties and satisfactory elasticity may be obtained by using 5—7% resol or 7—9% furfural base

(OUIER) 6/10

L. RADNOTI

resin, or 4-5% cresol base novolak combined with Igetex S3 latices. The hygroscopic resistance of fibra leather sheets can be improved approx 20-25% by the use of cresolic type novolak resins or approx 50% by the use of resols. Resins prepared by the acid condensation of phenol-formaldehyde-novolak produce sheets of excellent strength properties but of poor extensibility and excessive brittleness, which prohibit their use. On the other hand phenolic type resins (without latex) are excellent bonding agents for sheets used in the manufacture of fancy goods and bags for industrial purposes; compactness, stiffness, bulk, good strength properties, good hygroscopic resistance and limited elasticity are the requirements which must be fulfilled.

RADNOTE, E.

92. Improving the quality of fibre leather — L. Rad-
nóti, L. Fenyő. (*Lőr- és Cipőtechnika* — Vol. 4,
1954, No. 6, pp. 181—185, 3 tabs.)

The conditions for producing a uniform, high-grade
fibre leather are the following: adequate preparation of
the raw material, grinding or shredding of the fibres,
even distribution (precipitation) of the bonding material
on the surface of the fibres, the formation of sheets,
properly and gradually effected dewatering, and uniform
drying. The extent of grinding is characterized by
Schopper degrees. In order to obtain a high-grade product
the fibres must be ground to 70—75 degrees for
vegetable tanning. Fibre concentration should be max
1.8—2%, and the optimal temperature of the fibre sus-
pension is 20—22° C.

Title : Retanning of Vegetably Tanned Leather Fibers in
Leather Board Manufacture.

Orig Pub: Bör- és cipőtechnika, 1957, 7, No 2, 47-50.

Abstract: Waste leather was retanned with Al and Cr salts after
the tannides had been removed. For example, a 10 to
15%ual $\text{Al}_2(\text{SO}_4)_3$ solution was alkalized with soda
to the alkalinity of 25 to 30% at 35 to 40° before the
tannage; in order to avoid the formation of Al soap,
leather should be washed thoroughly before oiling.

AUTHOR: Radó, Aurél

TITLE: Study of the photographic action of some antifog agents

PERIODICAL: Referativnyy zhurnal, Fizika, no. 8, 1962, 27, abstract 8G242
("Kép- és hangtechn.", 1961, v. 7, no. 6, 166 - 169, Hungarian;
summary in German)

TEXT: The mechanism and the principal rules of the action of antifog agents were investigated on two different types of emulsion - silver chlor-bromide and silver bromiodide. Benzotriazole, diphenyl iodonium nitrate, and 1-phenyl-5-mercapto tetrazole were used as the antifog agents. It became evident from a comparison of their action on sensitivity and fog that the necessary condition for their action was their adsorption on the AgHal surface, presumably on the sensitivity centers. The antifog agents, in being adsorbed on the sensitivity centers, do not disturb their normal functioning during the time of exposure, but prevent them from reaching the fog centers during storage. Since there exist several types of sensitivity centers differing in chemical nature and re-

Study of the photographic action of some antifog agents A061/A101

In actions, it has been specifically established that the adsorption of antifog agents is significant only for such sensitivity centers (more precisely, such emulsions) as are oxidized by potassium bichromate. In addition to inhibiting the formation and growth of fog, the antifog action also lowers the speed of both image and fog development.

Let D be a plane domain bounded by the closed analytic curve Γ . Assume the functions $p=p(\xi, \eta)$, $q=q(\xi, \eta)$, $r=r(\xi, \eta)$ are bounded integrable functions defined in D ; and $A(\sigma)$, $B(\sigma)$ are bounded integrable functions defined on I' with A such that $\int_{I'} A(\sigma) d\sigma \neq 0$. The authors show that for ϵ sufficiently small there exists a function $u=u(\xi, \eta)$ which in D satisfies the equation

$$[1+\epsilon p] \left[\frac{\partial^2 u}{\partial \xi^2} + \frac{\partial^2 u}{\partial \eta^2} \right] + \epsilon \left[q \frac{\partial u}{\partial \xi} + r \frac{\partial u}{\partial \eta} \right] = 0$$

and which on Γ meets the condition

$$\frac{du}{dn} = \epsilon [A(\sigma)u + B(\sigma)].$$

The solution u admits a representation of the form

$$u = u_0(\xi, \eta) + u_1(\xi, \eta) + \epsilon^2 u_2(\xi, \eta) + \dots$$

Conditions for Linear Dependence of Three Functions
 Radu, Francisc. Conditions de dépendance linéaire
 pour trois fonctions. Acad. R. P. Romine. Fil. Cluj.
 Stud. Cerc. Sti. Ser. I. 6 (1955), no. 3-4, 51-63. (Romanian. Russian and French summaries)

In this paper, the author shows that the functions $F(x)$, $G(x)$, and $H(x)$, defined and continuous for $-\infty < x < +\infty$, are linearly dependent provided that (i) they vanish simultaneously only at isolated points and (ii) they satisfy the equation

$$\begin{vmatrix} F(x) & F(x+h) & F(x+2h) \\ G(x) & G(x+h) & G(x+2h) \\ H(x) & H(x+h) & H(x+2h) \end{vmatrix} = 0$$

for all real x and h . [See the preceding review.] The result follows from the theorem that if

$$a_n = \begin{pmatrix} \alpha_n \\ \beta_n \\ \gamma_n \end{pmatrix} \quad (n=0, 1, \dots)$$

is a sequence of vertical vectors, with α_n , β_n , and γ_n real numbers satisfying $\alpha_n^2 + \beta_n^2 + \gamma_n^2 \neq 0$, and if the determinant $|a_{n-k} \ a_n \ a_{n+k}|$ vanishes for $0 < k \leq n$, $n=1, 2, \dots$

then in the sequence $\{a_n\}$ there is a subsequence such that (i) the determinant formed by any three arbitrary vectors of the subsequence vanishes and (ii) of any two consecutive terms of the sequence $\{a_n\}$ at least one appears in the subsequence.

AUTHOR: Radó, F.

TITLE: Approximate calculation of the extrema of a function

PERIODICAL: Referativnyy zhurnal, Matematika, no. 11, 1962, 4, abstract 11B10
(Matematica (RPR), 1961, v. 3, no. 1, 171 - 166; French).

TEXT: Let $f(x)$ a real function defined on the interval $I_0 = [a, b]$ have a unique minimum at $x = x_0$. The points $c, d \in I_0$; $c < d$. 1) If $f(c) < f(d)$ then $x_0 \notin [a, d]$; 2) if $f(c) \geq f(d)$ then $x_0 \notin [c, b]$. In the former case we shall denote the segment $[a, d]$ as I_1 , in the latter case the same notation will be attributed to the segment $[c, b]$. Let us choose a point $\xi_1 \in I_1$. The segment I_1 is divided by the points ξ_1, x_0 into three parts. The totality of the two contiguous of these portions containing x_0 we shall denote as I_2 . In this manner one constructs a sequence of segments $I_0 \supset I_1 \supset I_2 \supset \dots \supset I_n \supset \dots \supset x_0$. Evidently, such a sequence is not uniquely determined. A sequence of segments whose lengths we shall denote as l_n and which, defined by the points c, d , and ξ_n , is called optimal if for every different choice of the points c, d ,

Approximate calculation of the extrema of a function

and one obtains a sequence of segments with lengths λ_n for which it is possible to find a positive integer N such that for $n > N$ the inequality $l_n \leq \lambda_n$ holds. The first theorem proven gives a method of constructing an optimal sequence of segments (using division by the mean and extreme ratio) and it is demonstrated that such a sequence is unique. $L(x_1, x_2, x_3; f|x)$ denotes the interpolation polynomial for $f(x)$ with three points x_1, x_2, x_3 . The value of x , at which $L(x_1, x_2, x_3; f|x)$ has a minimum, is denoted by d . It is equal to:

$$d = \frac{1}{2} \frac{(b^2 - c^2) f(a) + (c^2 - a^2) f(b) + (a^2 - b^2) f(c)}{(b - c) f(a) + (c - a) f(b) + (a - b) f(c)} . \quad (1)$$

The process of constructing an optimal sequence indicated in theorem 1 is modified by means of interpolation polynomials and the abscissae of their minima. A function is called convex of the second order if at $a \leq x_1 < x_2 < x_3 \leq b$, $L(x_1, x_2, x_3; f|x) < f(x)$ for $x_3 < x \leq b$. A proof is given for theorem 2. If $f(x)$ is convex of the second order, differentiable on $[a, b]$ and $a < c < b$, $f(c) < f(a)$, $f(c) < f(b)$, then on the segment $[a, b]$ $f(x)$ has a unique minimum at $x = x_0$, where $x_0 \geq d$ (the number d being defined by (1)), the equality

$x_0 = d$ being possible only when $d = c$. The author asserts that theorem 2 may be conveniently used for the numerical determination of extrema. There are no examples.
